EQ. 8 **Cyber Power** · central contribution

$$\mathrm{CP} = \min\{1, (\beta_1\,\mathrm{CS_m} + \beta_2\,\mathrm{CD_m} + \beta_3\,\mathrm{RC_m})(1 + \delta \cdot \mathrm{CDip})\}, \qquad \Sigma\,\beta_i = 1$$

$\mathrm{CS_m}$ Maritime cybersecurity

Protection of the digital assets of the maritime domain (AIS, ECDIS, GMDSS, naval C2, ports) through controls, threat analysis, and information sharing.

$\mathrm{CD_m}$ Strategic maritime cyberdefense

National, non-executional capacity: governance and strategy, defense cooperation, legal and doctrinal framework, science and technology, education, deterrent posture.

$\mathrm{RC_m}$ Maritime recovery capacity

Speed of restoration after a cyber incident, $\mathrm{RC_m} = \min\{1, t_{\mathrm{ref}}/t\}$; a time-based magnitude that bears on deterrence by futility.

CDip Cyber diplomacy

Projection in international norm-making and confidence-building fora. Amplifier only: it never reduces CP, and the saturation operator keeps CP ≤ 1.

Note: α is the weight of cyber dependence, a property of the maritime system; cyber maturity is read on CP itself in five bands. Raising CP always raises $\mathrm{MP_{norm}}$, whereas raising α raises it only if CP exceeds the geometric mean of the rest of the system, and lowers it otherwise (Proposition 1).
